

# Introduction to JavaScript

# Welcome

- JavaScript has many uses, but we will focus on Web Design, specifically how to add interactivity
- In this class there is an assumption that you are new to programming, but you know HTML and CSS

# What you can do with it

- JavaScript is a “real” programming language
  - Store variables
  - Set decision points
  - Loop
  - Reuse code with functions
- In addition
  - Get data from the browser
  - Manipulate the DOM that browsers use to create web pages

# Variables

- Store data and refer back to it later

# Decision Points

- Use control statements to decide which code to run under different circumstances

# Looping

- Avoid writing the same (or similar) code over and over again
- Determine at runtime how many times you want to run some code

# Functions

- Reuse code multiple times, but only write it once
- Use code from others

# Manipulating the DOM

- JavaScript can find, add, and delete elements from the DOM
- Can also react to mouse clicks, page reloads, and other actions

# Review

- A major component of learning any programming language is practice and repetition
- Expect to make mistakes
  - if you aren't you aren't learning

# DOM Review with Object Oriented Programming

# Web Pages are built upon the DOM

- Document Object Model
- Structures documents like a tree
- Every node has one parent, and possibly many children
- Nodes have properties, methods, and events

# Sample Document

# The DOM and JavaScript

- Page content is represented by the DOM
- Scripting languages (JavaScript) use the DOM to interact with the document

# How Does It Work?

- Accessing the DOM is done with an API – Application Programming Interface
  - No matter which browser, no matter which scripting language, the API is the same

# The DOM objects/elements

- **document** – the root of the page
  - `document.URI`, `document.height`, `document.links`, `document.bgColor`,....
- **element** – a node in the tree
  - Returned by a member of the API
- **nodeList** – an array (group) of elements
  - `document.getElementsByTagName('p')` would return a set of nodes
- **attribute**
  - A node in the DOM, though rarely used that way. Another way to manipulate/change the document

# Specific APIs

- `document.getElementById(id)`
- `document.getElementsByClassName(class)`
- `element.innerHTML`
- `element.style`
- `element.setAttribute(attribute, value)`
- `element.removeAttribute(attribute)`

# Review

- As you learn more JavaScript, you will be able to use the APIs
- We will start slow, but the important part is to eventually feel comfortable searching for these tools

# Newer DOM methods

**querySelector and querySelectorAll**

# Selecting the First Element

- `getElementById()` takes a single parameter and that parameter must be an id selector
- `querySelector()` Method
  - returns first result of the given selector which could be *anything* – except pseudo-elements
- Because the selector can be anything which is a valid CSS selector you must include the `#`, `.`, etc.

# Selecting Multiple Elements

- The `querySelectorAll()` method is identical to the `querySelector()` but returns all the found values
- Again, while `getElementsByClassName` doesn't need the `"."` as part of the selector, `querySelectorAll` does

# Deciding on a Method

- Speed won't be an issue for you
- querySelector allows you to use any css selector
- I am less prone to typos in the method name
- getElementById, getElementsByTagName, etc have more mnemonic names.
- I am less prone to typos in the css selector

# Output

# Interactivity

- HTML5 and CSS3 are not really interactive
- New elements and pseudo-classes can only go so far

# What Can JavaScript do?

- Read and write HTML elements
- Reacts to events (mouse events, keyboard events, etc.)
- Validate data
- Detect the visitor's browser
- Create cookies

# JavaScript Output

- JavaScript doesn't have a built-in print function
- Data is displayed via
  - an alert box using `window.alert()`
  - a prompt using `window.prompt()`
  - HTML output using `document.write()`
  - HTML element using `innerHTML()`
  - the browser console using `console.log()`

# alert()

- In JS, an alert is a pop-up window that displays information
- The parentheses mean that this is a function

```
alert("My Message Here")
```

# **prompt()**

- Very similar to alert, but wants input.

```
prompt("Enter your name: ")
```

# document.write()

- What if we want something permanent?
- document.write() writes directly to the page
- Here we have combined a function with an object that will add to page

```
document.write("Time to learn JavaScript")
```

# document.write()

- Not usually recommended since it can easily be misused

# innerHTML

- To change the contents of the DOM, use `innerHTML` combined with the element you want to change

no parentheses!!

```
element.innerHTML = "Time to learn JavaScript"
```

# console.log()

- This option write the data to the browser console
- The console is a place to see what is going on during the execution of your program

```
console.log("Leave a secret message")
```

# The console

- You should be utilizing the **console** by now
- Does more than take “print” statements, also provides debugging information for JavaScript, HTML and CSS

# Debugging

- **Safari:** Preferences → Advanced Check the Show development menu in menu box”
- **Google Chrome:** Developer → JavaScript Console
- **Firefox:** Tools→ Console
- **Edge:** F12

# Review

- Right now, we are doing simple things with output
- As you learn more, the power grows

# Variables

# Storing Data

- Part of learning to program is learning to store data
- In JavaScript, data is stored in variables
- To use a variable, you have to declare it

```
var name
```

keyword                          variable name

# Storing Data

Variable Name	Memory Location	Value “stored” in computer
name	11001100001101	“Christopher”
age	11001100001110	
...	11001100001111	
...	11001100010000	
...	11001100010001	
...	11001100010010	
...	11001100010011	

# Variable Names

- Consists of letters, digits, underscores, and dollar sign(\$)
- Can not start with a digit
- Are case-sensitive...
  - name Name, naMe, NAME are all different variables
- Should be mnemonic (meaningful)

# Variable assignments

- It is silly to have a variable if you are never going to use it
- You can assign values using the = operator

```
var name ="Colleen"
```

assignment operator

# Assignment statements

- I like to refer to the LHS and RHS of statements
- LHS – the variable being updated
- RHS – the new value that will be stored in the variable

```
var name  
  
name = "Colleen"
```

↑  
LHS

↑  
RHS

# Using a Variable

```
var name = prompt("What is your name?")
```

```
document.write(name)
```

```
var date= Date()
```

```
document.write(date)
```

```
var location= window.location
```

```
document.write(location)
```

# Review

- **Variables are a key component of creating interactive programs**
- **We will be using them in the remaining lectures so practice them and feel comfortable**

# Data Types

# Assignments

```
var name = prompt("What is your name?")
```

```
var name = Date()
```

```
var name = window.location
```

# Types

- In many programming languages, variables need to have a single type
- In JavaScript, a variable can take on many different types
- What are these types?

# Number

- Numerical values
  - with or without decimals

```
var width = window.innerWidth
```

```
var pi = 3.14
```

# String

- A String is a collection of characters (letters, numbers, punctuation, ....)
- To create a string you put the value in quotes "..."

```
var location = window.location  
  
var name = "Colleen"
```

# Boolean

- In programming, a boolean value is one that is either true or false

```
var status=false
```

```
var windowStatus=window.closed
```

- Later, we will learn how to write our own boolean expressions to check if things are true or false

# Object

- Sometimes the variables are more complex
  - A node in the DOM a good example

```
var topic= document.getElementById("myID")
```

- Nodes are more than a single value, they have attributes

# Array

- How can a function return more than one value?

```
var links= document.getElementsByTagName('a')
```

# Accessing Array Elements

- Arrays store multiple value using a variable name, and an index for each element in the array

```
var links= document.getElementsByTagName('a')  
  
document.write(links[0])
```

- We will cover arrays in depth later in the course

# Review

- Luckily in JavaScript you have a lot of flexibility with the types of data
- For now, focus on learning the types of data returned by the most common APIs

# Operators and Expressions

# Statements

- We have been using statements to execute our JavaScript code
- Statements often have *expressions*
- Expressions produce values

# Expression

- So if you think back to  $LHS = RHS$ , the LHS is a variable and the RHS is what generates the value
- What are our tools for generating values on the RHS?

# Assignment Operators

Operator	Example	Value stored in x
=	x = 5	5
=	y = 12 x = y	12

# Arithmetic Operators

Operator	Example	Value stored in x
+	$x = 2 + 5$	7
-	$x = 5 - 2$	3
*	$x = 2 * 5$	10
/	$x = 5/2$	2.5
%	$x = 5 \% 2$	1

# More Operators

Operator	Example	Value stored in x
++	x = 5; x++;	6
--	x = 12; x--	11
+=	x = 2; x+=5	7

# String Operators

Operator	Example	Value stored in x
+	x = "Hi" + "There"	"HiThere"
+	x = "Hi" + 5	"Hi5"
+=	x = "Hi" x += "There"	"HiThere"

# Boolean Operators

- We can also use operators to compare values
- Assume  $x = 12;$

Operator	Example	Returns
<code>==</code>	<code>x == 5</code>	false
<code>==</code>	<code>x == 12</code>	true
<code>!=</code>	<code>x != 5</code>	true

# Boolean Operators

- Assume  $x = 12;$

Operator	Example	Returns
$>$	$x > 12$	false
$\geq$	$x \geq 12$	true
$<$	$x < 12$	false
$\leq$	$x \leq 12$	true

# Boolean Operators

- Assume `x = 12;`

Operator	Example	Returns...
<code>==</code>	<code>x == "12"</code>	true
<code>====</code>	<code>x === "12"</code>	false
<code>!=</code>	<code>x != 12</code>	false

- You need to really stop and think about these operators...

# Logical Operators

- Assume  $x = 12;$

Operator	Example	Returns...
<code>&amp;&amp;</code>	$(15 > x) \&\& (x > 5)$ both sides must be true	true
<code>  </code>	$(15 > x)    (x > 5)$ at least one side must be true	true
<code>!</code>	$!(x == 12)$	false

# Review

- Programming is not just about knowing the syntax of a language
- You need to think about the logic behind what you want to do, before you start to code
